I²C-bus: the worldwide standard for IC communication

Philips was the inventor of the Inter-IC or I²C-bus nearly 20 years ago, and it is now firmly established as the worldwide de-facto solution for embedded applications. It is used extensively in a variety of microcontroller-based professional, consumer and telecommunications applications as a control, diagnostic and power management bus. As a two-wire serial bus, its inherently simple operation was crucial to its emergence as the worldwide de-facto standard. This simplicity has been retained in the enhancements to the original specification:

[Level-shifting operation](#) solution for mixed voltage environments; [Fast mode](#) offering speeds up to 400 kbits/s; and [High-speed mode](#)

Philips offers more than 150 [products with an I²C interface](#) and it has been adopted by about 50 licensees, with over 1000 I²C compatible devices in total.

For more background information, check out the [Facts & figures](#) page.

Apply for a license today!

Purchase of Philips I²C components conveys a license under the Philips I²C patent to use the components of the I²C system, provided the system conforms to the I²C specifications defined by Philips. Product News From Philips Semiconductors**Philips Semiconductors develops I²C-bus peripheral chip for software configuration of Pentium® II - processor type motherboards**

The price of upgradeability on PC motherboards has been the need to open up the computer case and alter dip switch or jumper link settings. A new I²C-bus peripheral chip from Philips Semiconductors makes this risky, time-consuming process a thing of the past

Designed to support Intel's Pentium II processor chip-sets, the PCA8550 multiplexer IC from Philips Semiconductors replaces mechanical dip switches and jumper links by software-controlled configuration settings. Using this innovative single-chip solution to 'jumperless' board design, manufacturers of PC motherboards and add-in cards can now offer users a much greater level of plug-and-play compatibility - eliminating any need for users to open up their PCs in order to reconfigure the hardware.

The [PDF](#) [PCA8550](#) is a 4-bit 1-of-2 multiplexer that selects between data applied to four of its input pins and the data stored in an on-chip non-volatile data register. Read/write access to the non-volatile register via the I²C-bus (System Management bus*) allows boards to be intelligently configured to suit different hardware and software requirements, either at power-up or 'on-the-fly' as programs run. Hardwired logic levels applied to the four multiplexer input pins provide the board with a set of 'fail-safe' default settings. The PCA8550's non-volatile register also contains a fifth 'latched' control bit that is available on a dedicated output pin and is guaranteed to be glitch-free during register read/write operations. The PCA8550 also features an override input that forces all the register outputs to zero, and a write-protect pin to enable/disable modification of the non-volatile register contents.

In addition to configuring motherboards for settings such as clock speed, clock multiplier and memory type, the PCA8550 can be used to provide intelligent reconfiguring of add-in cards. Manufacturers of networking, video and sound cards, which frequently require the changing of board settings to suit different hardware and software environments, will find the PCA8550 particularly useful in differentiating their cards from the competition.

Use of the PCA8550 not only benefits PC end-users. It also means that motherboard and add-in card manufacturers will be able to fully automate the testing of their boards, without the need for manual intervention or electro-mechanical devices to change jumper/dip-switch settings.

"Philips Semiconductors is proud to be the first company to provide a single-chip solution to jumperless board configuration," said Catherine de Villeneuve, general marketing manager for Philips Semiconductors' Logic Products Business Line. "As a key supplier to the PC marketplace, Philips is committed to advancing the scope of PC products and our close relationships with circuit board designers

provide many opportunities to share product concepts and specifications. This co-mingling of expertise will produce many unique, high calibre products both in the near and longer-term future," she added.

Commenting on this new product introduction, Dataquest senior industry analyst Geoff Ballew said, "The PCA8550 represents a new level of integration in motherboard and peripheral board control. Just as Intel is doing, other manufacturers and value added resellers of desktop and notebook PCs will want to incorporate Philips' software mux. In addition to addressing an outstanding hardware configuration issue with a simple software solution, the PCA8550 suggests more flexibility for remote systems management."

The PCA8550, packaged in an ultra-small 16-lead TSSOP (Thin Shrink Small Outline Package) is available now in high volume. It costs in the region of US\$ 0.80 in quantities of 10k or more pieces.

Philips Semiconductors, a division of Philips Electronics NV, headquartered in Eindhoven, The Netherlands, is the ninth largest semiconductor supplier in the world and the fourth largest supplier of discretes in the world. Philips Semiconductors' innovations in digital audio, video, and mobile technology position the company as a leader in the consumer, multimedia and wireless communications markets. Sales offices are located in all major markets around the world and are supported by systems labs.

*Philips Semiconductors, the largest European semiconductor manufacturer, invented the 2-wire I²C-bus in 1979 as a low-cost, easy to implement way of communicating between integrated circuits. Already widely adopted, it has come to be known in the PC industry as the System Management (SM) bus.

[Newsroom](#)[News archive](#)[Press contacts](#)[Newsletters & Articles](#)[In focus](#)[Subscribe to eNews](#)[Shows & Events](#)[Relevant Links](#)[Shows & Events](#)[Relevant Links](#)[Bus systems](#)[I²C](#)[1394](#)[Sales & distribution offices](#)**1997-12-02 , ESC-9727****Technology News From Philips Semiconductors****New bus enhancement from Philips Semiconductors reduces costs in mixed voltage system design**

Philips Semiconductors announced today a simple enhancement to its I²C-bus, the de-facto standard for communication between ICs. It provides a straightforward solution to the problem of allowing ICs with different supply voltages to communicate and be controlled, for almost no additional design-in effort or cost.

The two-wire I²C-bus is used in a wide range of microcontroller-based consumer and telecommunications products. Having been adopted by about 50 licensees, and with over 1000 different IC devices available today which include an I²C-bus interface, simplicity was crucial to its emergence as the worldwide de-facto serial bus standard. This latest enhancement, involving the addition of just two low-cost transistors, retains its essential simplicity while answering all communication needs in a complete multi-supply voltage system design. Manufacturers can thus easily integrate new 3.3-volt ICs into existing designs, to raise product performance or reduce power consumption, for almost no extra cost.

Although technically simple, this enhancement directly addresses an issue of growing importance in the electronics world: mixing ICs with different supply voltages in one design. This has come about because of the trend towards lower power consumption and the use of very fine line-widths on the latest VLSI and ULSI devices, which necessitates a reduction in supply voltage for new ICs. These have to operate with the vast array of existing 5 V designs and the level shifting solution allows simple integration, without having to re-design the complete system to operate at 3.3 V and ensuring 100% compatibility between all I²C ICs, regardless of supply voltage.

"This new capability of shifting between voltage levels for the I²C-bus gives designers and manufacturers a simple, effective solution for mixed voltage designs in terms of performance and cost, while maintaining the versatility and simplicity of the I²C-bus", said Theo Claasen, Philips Semiconductors' chief technology officer. "At the same time, the I²C-bus specification has been extended to cover devices operating below 2.7 V, ensuring that the I²C-bus will remain the serial bus of choice for future systems into the next century."

Philips Semiconductors, a division of Philips Electronics NV, headquartered in Eindhoven, The Netherlands, is the ninth largest semiconductor supplier in the world. Philips Semiconductors' innovations in digital audio, video, and mobile technology position the company as a leader in the consumer, multimedia and wireless communications markets. Sales offices are located in all major markets around the world and are supported by systems labs.

1997-12-09, ESC-9727 Backgrounder Technical Backgrounder From Philips Semiconductors Level-shifting I²C specification simplifies mixed voltage designs

There is a strong drive worldwide to reduce supply voltages below 5 V for new IC devices. Already, 3.3 V is used widely and even lower voltages will be employed in the future. However, 5 V devices are still very common today and will continue to be used for some time yet, because of the sheer number and variety of 5 V devices available, as well as the increasing need to incorporate 'higher voltage' analog and power I/O into systems. This need to mix supply voltages can complicate the design of new systems significantly.

When mixing devices with different supply voltages within one design, a standard solution is to use level-shifters. However, in the case of the I²C-bus standard level-shifters cannot be used, because signals are bi-directional and there is no 'direction' indication signal on the bus. But in designing a level-shifting solution for the I²C-bus, Philips wanted to preserve the elegance and simplicity that made the I²C-bus the de-facto standard it is today.

The bi-directional level-shifter consists of an N-channel enhancement MOSFET which interconnects two sections of an I²C-bus system, each section with a different supply voltage and different logic levels. Referring to figure 1, three states have to be considered:

1. No device is pulling down the bus line; the bus line of the 'lower voltage' section is pulled up by its pull-up resistors to 3.3 V and the bus line of the 'higher voltage' section is pulled up to 5 V. The MOSFET is not conducting.
2. A 3.3 V device pulls down the bus line to a LOW level; the MOSFET becomes conducting and the bus line of the 'higher voltage' section is also pulled down.
3. A 5 V device pulls down the bus line to a LOW level; in first instance the diode and then the MOSFET become conducting and the bus line of the 'lower voltage' section is also pulled down.

In each case, a simple analysis of the circuit shows that the logic levels are transferred in both directions of the bus system, independent of the driving section.

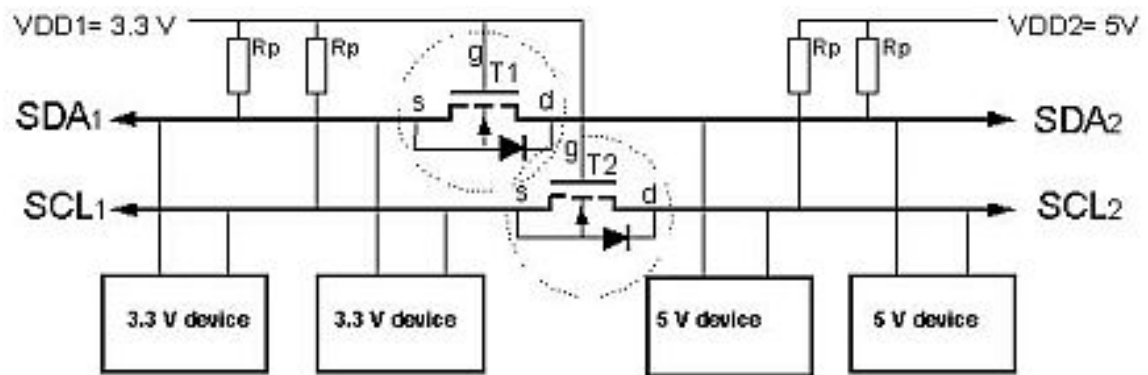

Figure 1. Bi-directional level-shifter circuit connects two different voltage sections of an I²C-bus system.

Depending on the MOSFET parameters, the level-shifter can cover a wide range of supply voltages - from as low as 2 V and higher than 5 V if desired. The values of pull-up resistors (and possible series resistors between I/O pins and bus lines) depend on worst case values of the supply voltages and logic levels, the length and load of the bus lines, and rise and fall time requirements. These have to be calculated for each bus system separately. Their values must be chosen in such a way that there is sufficient noise margin at both HIGH and LOW levels.

This approach not only provides a level-shifting function for the I²C-bus for all voltage and logic levels, it also provides two additional functions. First, the 'lower voltage' section can be powered-down, effectively removing it from the bus system and allowing the powered 'higher voltage' section to operate normally. Second, it provides a high level of protection to the 'lower voltage' section against voltage spikes produced at the 'higher voltage' section, as long as the MOSFET itself can withstand these spikes.

By simply adding another MOSFET on each bus line (see figure 2), an extended power-down structure is achieved. Additional sections with a higher, lower or similar supply voltage can be added by simply connecting them via additional MOSFETs to the common drain terminals. Each individual section can be isolated from the rest of the bus system when its supply voltage is switched off, while level-shifting between all other sections remains operational. VDD3 and the dotted pull-up resistors, which establish a defined level at the common drain connections, are optional.

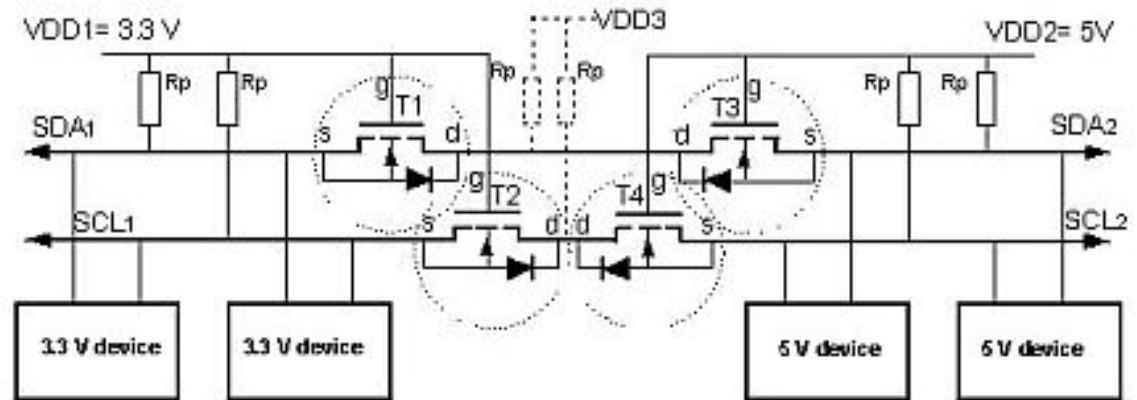

Figure 2. I²C-bus system in which the 'higher voltage' section is isolated at power-off.

In addition, the present I²C-bus specification has been extended to cover lower supply voltages and the I²C-bus can now be used for all new devices operating below 2.7 V. Using the low-cost level-shifting solution, these new devices can be kept 100% compatible with devices working at different supply voltages. In fact, in systems relying only on the I²C-bus for inter-IC communication, only two transistors are needed for each separate supply to keep wiring to the absolute minimum (two wires per device). This further enhances the advantage of the I²C-bus over solutions with more signals or random direct connections, because not only is the wiring itself less complex but also substantially fewer level-shifting components are needed. This ensures that I²C-bus applications will continue to expand into the next century.

Philips [+ INFO](#) [BSN10](#), [+ INFO](#) [BSN20](#) and [+ INFO](#) [BSS83](#) MOSFETs are all suitable for this level-shifting function.

About the I²C-bus

- [What is the I2C-bus?](#)
 - [Level-shifting I2C](#)
 - [Fast-mode I2C](#)
 - [High-Speed mode I2C](#)
 - [10-bit I2C addressing](#)
- [The I2C-bus specification](#)

What is the I²C-bus?

In modern electronic systems there are a number of peripheral ICs that have to communicate with each other and the outside world. To maximize hardware efficiency and simplify circuit design, Philips developed a simple bi-directional 2-wire, serial data (SDA) and serial clock (SCL) bus for inter-IC control. This I²C-bus supports any IC fabrication process and, with the extremely broad range of I²C-compatible chips from Philips and other suppliers, it has become the worldwide industry standard proprietary control bus.

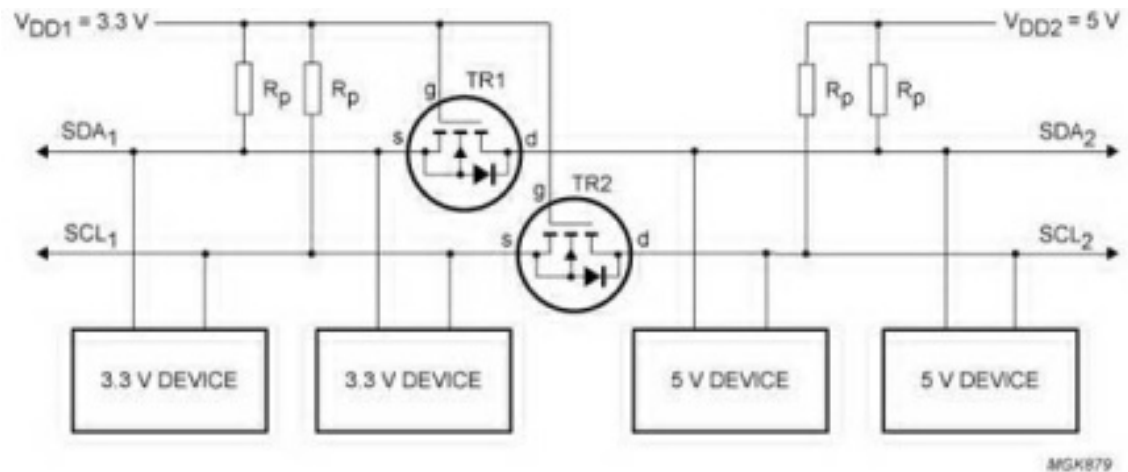

Each device is recognized by a unique address and can operate as either a receiver-only device (e.g. an [LCD driver](#) or a transmitter with the capability to both receive and send information (such as [memory](#)). Transmitters and/or receivers can operate in either master or slave mode, depending on whether the chip has to initiate a data transfer or is only addressed. I²C is a multi-master bus, i.e. it can be controlled by more than one IC connected to it.

The basic I²C-bus, with a data transfer rate up to 100 kbits/s and 7-bit addressing, was originally introduced nearly 20 years ago. But, as data transfer rates and application functionality rapidly increased, the I²C-bus specification was enhanced to include [Fast-mode](#) and [10-bit addressing](#), meeting the demand for higher speeds and more address space.

The I²C-bus continues to keep pace with advancing technology while retaining its backwards compatibility. Mixed designs incorporating new low voltage devices are supported via the I²C-bus' [level shifting capability](#). And, most recently,

High-speed mode has been added; with speeds of up to 3.4 Mbits/s it ensures the capacity of the I²C-bus to support existing and future high speed serial transfer rates for applications such as EEPROM and Flash memory.

Level-shifting I²C

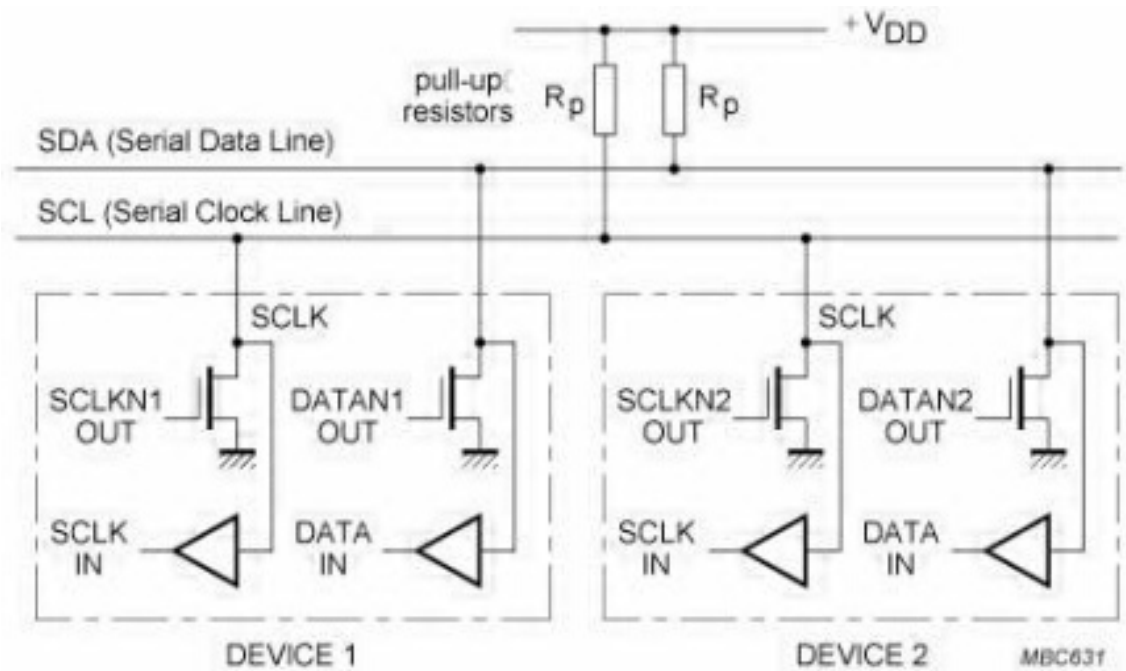

Philips Semiconductors has developed a simple 'level-shifting' enhancement to the standard I²C-bus, offering fully bi-directional data transfer between I²C-devices operating from different supply voltages. It provides an elegant solution for allowing ICs with different supply voltages to communicate and be controlled, for almost no additional design-in effort or cost.

The simple addition of two low-cost transistors, placed between the different voltage level sections of the I²C-bus, separates and transfers the logic voltage levels of the bus lines on either side of the level-shifter. In fact, with the addition of these transistors, the I²C-bus answers all level-shifting needs for a complete multi-supply voltage system design. This set-up also allows the level-shifter to be used to isolate a section of powered-down devices from the bus, allowing powered I²C devices to operate normally.

At the same time, the I²C-bus specification has been extended for devices operating below 2.7 V. This extension, together with compatibility of lower and higher voltage devices provided by the bi-directional level-shifter, ensures the I²C-bus will remain the serial bus of choice for future systems into the next century.

Fast-mode I²C

Until 1992, the I²C-bus was mainly used for the transfer of control and status information and its originally defined bit rate of 100 kbits/s remained sufficient for this purpose. As it became a de-facto standard, it began to be used for text and data transfer and to meet these needs, in 1992 the specification was upgraded with a Fast-mode, supporting bit rates up to 400 kbits/s. Compatible with Standard-mode devices, all Philips Semiconductors devices developed since 1992 have included a Fast-mode I²C-bus interface. Support for even higher data transfer speeds is now available through [High-speed mode](#) (which also offers the [level-shifting](#) enhancement).

High-speed mode I²C-Bus

Developments in high-speed serial RAMs and mixed technology telecom systems have created a demand for buses capable of operating at high speeds and with a variety of supply voltages. I²C's High-speed mode meets these needs without sacrificing its compatibility with existing Standard and Fast-mode devices or its low-cost simplicity - no special logic levels, timing or drive capability are needed.

A purpose-designed bridge in a High-speed mode master allows for bi-directional communications between Fast- and Standard-mode devices within a single I²C-bus system and, if required, this master can also perform bi-directional level shifting, supporting a variety of different voltage devices.

As a true multi-master bus, I²C's High-speed mode requires no additional wires or pins for slave devices. Also, there are two additional pins on a High-speed master which, if they are not used (because there is no system bridge or only Fast/Standard-mode are in use), then other I/O functions can be assigned to these pins, making I²C an extremely flexible solution.

10-bit I²C addressing

10-bit addressing allows the use of up to 1024 additional addresses to prevent problems with the allocation of slave addresses as the number of I²C devices rapidly expands. It does not change the format for addresses defined in the I²C-bus specification, using addresses reserved in the existing specification.

10-bit addressing does not affect the existing 7-bit addressing, allowing devices with 7-bit or 10-bit addresses to be connected to the same I²C-bus, and both

types of devices can be used in Standard-, Fast- or High-speed mode systems.

I²C-bus specification

The latest update to the I²C-bus specification, version 2.0, includes full details of the standard I²C-bus interface plus specifications for all the enhancements including Fast-mode, High-speed mode, 10-bit addressing and details on the bi-directional level shifter.

Please check with your nearest [sales or distributor office](#) status and availability of devices listed on this page.

Description

N-channel enhancement mode vertical D-MOS transistor in a TO-92 envelope, intended for use in general purpose fast switching applications.

Features

- Direct interface to C-MOS, TTL, etc.
- High-speed switching
- No secondary breakdown.

Datasheet

**Description** ▲

N-channel enhancement mode vertical D-MOS transistor in a SOT23 SMD package.

Features ▲

- Direct interface to C-MOS, TTL, etc.
- High-speed switching
- No secondary breakdown.

Applications ▲

- Thin and thick film circuits
- General purpose fast switching applications.

Datasheet ▲

**Description** ▲

Symmetrical insulated-gate silicon MOS field-effect transistor of the N-channel enhancement mode type. The transistor is sealed in a SOT143 envelope and features a low ON resistance and low capacitances. The transistor is protected against excessive input voltages by integrated back-to-back diodes between gate and substrate.

Applications ▲

- analog and/or digital switch
- switch driver
